#### **MEMORANDUM**

October 11, 2017

To: Grandview Estates Rural Water Conservation District

From: Rhett Everett, Hydrologist, and Suzanne Paschke, Ph.D., USGS, Lakewood, CO

Subject: Grandview Estates Groundwater-Level Monitoring report through August 2017

This memorandum from the U.S. Geological Survey (USGS) to the Grandview Estates Rural Water Conservation District (GERWCD) reports: (1) groundwater levels measured in selected GERWCD Denver Basin domestic wells from 2009 thru August 2017, (2) continuous water level and selected water-quality properties from 2014 thru August 2017, and (3) groundwater-quality results and estimated groundwater-age results for two GERWCD domestic wells sampled in 2004 and 2005 as part of the USGS National Water Quality Assessment Program (NAWQA). This memorandum summarizes all data collected in Grandview Estates since 2004 and supersedes all previous progress reports.

## Introduction

Grandview Estates is a rural-residential subdivision, first established in the 1950s, of 1 to 2-acre lots located approximately two miles west of Parker, Colorado (fig. 1). Residents of Grandview Estates rely on domestic wells for water supply, and the GERWCD is responsible for oversight of water resources for the subdivision. Review of the Colorado State Division of Water Resources well-permit database indicates Grandview Estates domestic wells are primarily completed in the Dawson and Denver aquifers, which are the uppermost layers of the Denver Basin aquifer system in this area. Surrounding municipal wells are completed in the Dawson, Denver, Arapahoe, and Laramie-Fox Hills aquifers of the Denver Basin aquifer system. Concern for the effects of pumping on water levels in Grandview Estates domestic wells led to a cooperative water-level monitoring project between GERWCD and the USGS.

In 2009, a water-level monitoring network of 14 domestic wells (six completed in the Dawson aquifer, eight completed in the Denver aquifer) was established in Grandview Estates, and water levels were measured on a regular basis. In 2010, one Dawson well was dropped from the network and six additional domestic wells, all completed in the Dawson aquifer, were added to the water-level monitoring network to provide additional water-level measurements prior to the

construction of Chambers Reservoir. In 2011, one additional well completed in the Dawson aquifer was added to the network. In December 2011, transducers were installed in two wells and were programmed to record water levels on an hourly basis. In June 2013, one Dawson well was dropped from the network at the owner's request. In June 2014, one well was equipped with instrumentation to automatically measure and record the depth to water, water temperature and specific conductance at regular time intervals. In February 2016, one Denver well was dropped from the network when the property could no longer be accessed. In February 2017, two wells in the Dawson aquifer along 6<sup>th</sup> St. were added to the network. To date, water levels are routinely measured in 20 domestic wells in the Grandview Estates; 13 wells are completed in the Dawson aquifer, and 7 wells are completed in the Denver aquifer.

In 2004 and 2005, water-quality samples were collected by the USGS from two domestic wells in the Grandview Estates subdivision as part of a National Water Quality Assessment (NAWQA) Program water-quality characterization study in the Denver Basin.

## **Methods**

Wells were selected for the Grandview Estates monitoring network based on well construction information and well accessibility. First, the GERWCD provided the USGS with a list of residents who had volunteered their wells for monitoring. The USGS then queried the Colorado Division of Water Resources well-permit database (http://www.dwr.state.co.us/WellViewWeb/) and examined well-drilling records in the permitting documents to determine which wells were considered suitable for water-level monitoring. Wells were considered suitable for water-level monitoring if the screened-interval depth and well-construction materials were known from the well-drilling records and if the well was accessible. Consideration also was given to the spatial distribution of the wells. Wells were chosen such that they were spread geographically across the subdivision and such that water levels could be monitored in both the Dawson and Denver aquifers beneath the subdivision. Well owners (some were the previously mentioned volunteers) were contacted and access permission was requested as suitable wells were identified from the well-permit database. Fourteen domestic wells were initially chosen for the water-level monitoring network (table 1; fig. 2). Six of the selected wells are completed in the Dawson aquifer, and eight of the selected wells are completed in the Denver aquifer. Each well was visited by Jim Collins of the USGS in January 2009 to confirm site access and to measure and record the latitude, longitude, measuring-point height, and land-surface altitude at each well.

Water levels were measured and recorded to within 0.01 feet (ft) by using a calibrated steel tape, whenever possible, following procedures outlined by Cunningham and Schalk (2011) (with the exception that a break-away weight was not used because of the concern the weight could become tangled in the pump wiring). When conditions such as inclement weather or the presence of condensation within the well casing prohibited the use of a steel tape, a calibrated electric tape

was used instead. Depth-to-water measurements were made from the measuring point, typically the top of the steel surface casing or well cap. To verify that the water level in the well was under static conditions, consecutive measurements were made until two measurements were within 0.02 ft of one another or the reason for lack of agreement was determined. If consecutive measurements indicated the water level was rising, or recovering, the shallowest measurement was used and remarked with a status of "R" for recently pumped. If consecutive measurements indicated the water level was slowly falling, or declining, the shallowest measurement was used and marked with a status of "S" for nearby pumping. If multiple measurements showed no trend but were within 0.1 ft of each other, the average of the measurements was used. If a pump was operated during a visit, the water level was allowed to recover for approximately 10 minutes until a measurement was made. If a pump was cycling during a visit, the tape was held in place during the recovery period until the pump turned on again and this single highest level was recorded. Depth to water below land surface was calculated by subtracting the measuring point (MP) height above land surface from the depth to water below the MP. The tape is disinfected with Clorox wipes between wells.

Pressure transducer instrumentation included two In-Situ Level TROLL 500 vented 30 pound per square inch pressure transducers equipped to record the depth to water and one In-Situ Aqua TROLL 200 vented 15 pound per square inch pressure transducer equipped to record depth to water, temperature, and specific conductance. Both types of probes have a pressure/level sensor accuracy, as rated by the manufacturer, of plus or minus 0.05 percent of the full scale at 15 degrees Celsius (°C) and a built in data logger (In-Situ Inc., 2015a). The Aqua Troll has a conductivity sensor accurate to 1 microsiemens per centimeter at 25°C (µs/cm) when reading under 80,000 μs/cm and a temperature accuracy of 0.1 °C. The transducers were suspended in the well on a vented communication cable that allowed downloading the data without disturbing the probe. Once the transducer was in place, it was calibrated to a manual water-level measurement (depth below land surface) and programmed to record a water level every hour. The manual water-level measurements are used to calibrate the time-series water-level data and correct for instrument drift. The specific conductance probe is checked in a standard conductance solution of either 750 or 1,000 (µs/cm) during each visit, and the difference is used to correct the data. The temperature probe is calibrated at the factory, and the field values are not checked for calibration purposes. Graphs of the time-series data presented in this memorandum include the daily maximum groundwater elevation (Appendix 1), which is the highest of a given day's 24 observations. The daily maximum groundwater elevation most often occurs when nearby pumping is at its lowest (usually during the early morning hours) and is most representative of the static water level. In some cases, the manual measurement (circle or triangle) plotted along with the time-series data is lower than the time-series daily maximum value. This slight difference observed on the graphs occurs because the instantaneous manual measurement is not always the daily maximum observation recorded by the data logger.

Water-quality samples were collected from two domestic wells in the Grandview Estates subdivision during 2004 and 2005 as part of the USGS NAWQA program. Site 393227104490101 is completed 300-340 ft below land surface in the Dawson aquifer, and site 393227104493001 is completed 361-441 ft below land surface in the Denver aquifer. Samples from both wells were analyzed for field parameters, major ions, and indicators of groundwater age including tritium, and chlorofluorocarbons. Samples from the Dawson well were additionally analyzed for trace metals, volatile organic compounds, and pesticides. Sampling and analytical methods followed standard USGS procedures.

### Results

Site information and water-level data for all 21 domestic wells in the Grandview water-level network are accessible from the USGS National Water Information System (NWIS) database (http://nwis.waterdata.usgs.gov/co/nwis/gwlevels) by searching for data using the USGS Site Numbers listed in table 1. A summary of water-level measurements collected to date including the period of record, number of measurements, and maximum and minimum observed water levels are presented in table 2. All discrete water-level measurements and a comparison to the initial measurement and to the water level measurement from the previous year are presented in table 3. A bar graph showing average year-to-year changes in manual water-level measurements for each aquifer is shown in figure 4. The average change in seasonally high water level and average year-to-year change in water level for all measurements by aquifer is presented in table 4. Hydrographs showing temporal changes in water levels for individual wells from 2009 through August 2017 are shown in Appendix 1. Potentiometric water-level maps of the highest water levels in 2011 (January) and the lowest water levels in 2011 (September) for the Dawson and Denver aquifers are presented in Appendix 2.

In general, water levels in the monitored domestic wells display a seasonal pattern with the highest water levels occurring during the winter and the lowest water levels occurring during the summer. Water levels measured during the summer months are expected to be less than those measured during other seasons because of increased groundwater pumping for lawn irrigation during the summer. Water levels in most wells completed in the Dawson aquifer were highest during the spring of 2016 and lowest during the summer of 2012. In general, water levels exhibit a pattern of water-level decline from 2009 through 2013 followed by an increase through the spring of 2016 (table 4) (Appendix 1). Water levels in most wells completed in the Denver aquifer were highest during the winter or spring of 2010 and lowest during the summer 2012, and, in about half of the wells measured, both the winter maximum and summer minimum water levels exhibit a pattern of water-level decline for the period of record. The highest water levels observed since 2009 occurred during the spring of 2017 in four of the wells (GRNDAW2, GRNDAW8, and GRENDEV7) (table 2). The lowest water levels measured since 2009 were observed in three wells (GRNDAW7, GRNDAW8, and GRNDEV 6) in August 2017

(table 2). Because GRNDAW7 and GRN<u>DAW8</u> were added to the network in 2017 (table 3), the highest and lowest observed water levels in the GRNDAW7 and GRNDAW8 wells are simply caused by the short period of record at these wells. Water levels at GRNDAW2 and GRNDEV7 have been on a steady rise since the fall of 2013 with the previous highest water level in both wells occurring in June 2016.

#### 2009

In 2009, water-level measurements were made in 14 wells (6 Dawson, 8 Denver) in January, March, July, September, and November. Changes in water levels over the monitoring period are generally less than 30 ft in magnitude. The maximum change from January 2009 conditions was 28.9 ft of drawdown measured at well GRNDAW1 during the September water-level measurements. Water-level changes from January to September 2009, are variable, ranging from the maximum drawdown of 28.9 ft to a water-level rise of about 9 ft at well GRNDEV4 in July 2009. All of the wells except one (GRNDAW2) exhibited drawdown over the summer. About 5.5 ft of water-level rise was observed at well GRNDAW2. These observed water-level differences may be caused by recent pumping at the measured well, local pumping within the subdivision, or pumping from outside the subdivision.

#### 2010

In 2010, bimonthly water levels were made in January, March, May, July, September, and November. In 2010, six additional domestic wells, all completed in the Dawson aquifer, were added to the water-level monitoring network (table 1; fig. 1) to provide additional water-level measurements prior to the construction of Chambers Reservoir. Five of the new wells are located in the northeast corner of Grandview Estates, along North 6<sup>th</sup> Street, and one of the wells is located in the southeast quarter, along North 5<sup>th</sup> Street. Three of the wells were added in May, two in July, and one in September 2010. Measurements were discontinued at one well in the Dawson aquifer (GRNDAW5) in July 2010 when the residence was sold.

Comparison of January (representing the seasonal high) manual water-level measurements in 2009 and 2010 shows that water levels declined in four of the wells and rose in nine. While the amount of the change varied by well and location, decline in the Dawson aquifer averaged 1.8 ft and a rise in the Denver aquifer averaged 8.1 ft (table 4). From January 2009 to 2010, the greatest decline in the Dawson aquifer of about 18.5 ft was observed in GRNDAW1, and the greatest decline in the Denver aquifer of about 21.8 ft was observed in GRNDEV2. Comparison of all year-to-year changes in manual water-level measurements for all wells in an aquifer indicates decline in the Dawson aquifer averaged 2.5 ft and decline in the Denver aquifer averaged 1.3 ft (table 4). During the fall and winter months, water levels recover from summer pumping with the highest water levels observed during the spring months of March through May prior to the following irrigation season. From September 2009 through March 2010, water-level rise was observed for all of the wells in the water-level monitoring network, except GRNDEV2.

In general, water levels in the monitored domestic wells were lowest during the summer and fall of 2010 and were increasing to November 2010. Water levels measured during the summer months are expected to be less than those measured during other seasons because of groundwater pumping for lawn irrigation, and the maximum drawdown (negative difference from January 2009 measurement) of 43.2 ft was measured at well GRNDEV2 during the September 2010

water-level measurements. Drawdown was observed during the summers of 2009 and 2010 at all of the wells except one (GRNDAW2). About 5.5 ft of water-level rise was observed at well GRNDAW2 in 2009 and 1.5 ft in 2010. Well GRNDAW2 is the shallowest well in the water-level monitoring network, completed 40-160 ft below land surface. Reduced pumping or lawn-irrigation return flows in the vicinity of GRNDAW2 could be contributing to the water-level rise at this location. From September 2009 through March 2010, water-level rise was observed for all of the wells in the water-level monitoring network, except GRNDEV2. The recovery of winter 2010 water levels to values greater than or equal to winter 2009 measurements indicates that bedrock potentiometric conditions beneath Grandview Estates are likely responding to decreased pumping during the winter months and possibly to increased precipitation recharge experienced during the fall of 2009 (http://www.crh.noaa.gov/bou/?n=denclim\_monthly\_annual). Water levels measured at GRNDEV 6 are consistently lower by as much as 200 ft from nearby wells. Well GRNDEV 6 has the deepest completion of all other wells in the network, completed 580-680 ft below land surface.

#### 2011

In 2011, water levels were made in January, March, May, July, and September. Funding was suspended in November 2011. One additional well (GRNDAW2b) was added to the network in May 2011. Measurements were suspended at one well in the Dawson aquifer (GRNDAW2) in July 2011 when the residence was sold, water-level measurements in this well were resumed in October 2012 with permission from the new owner. In December 2011, transducers were installed in two wells (GRNDAW4, GRNDEV3) as part of the cooperative project between the USGS and the Rural Water Authority of Douglas County. The transducers were programmed to record water levels on an hourly basis.

Comparison of January (representing the seasonal high) manual water-level measurements in 2010 and 2011 shows that water levels declined in all 13 wells that were measured. Decline in the Dawson aquifer averaged 5.6 ft and decline in the Denver aquifer averaged 7.3 ft (table 4). From January 2010 to 2011 the greatest decline in the Dawson aquifer of about 23.7 ft was observed in GRNDAW4, and the greatest decline in the Denver aquifer of about 21.8 ft was observed in GRNDEV6. Comparison of all year-to-year changes in manual water-level measurements for all wells in an aquifer indicates decline in the Dawson aquifer averaged 5.0 ft and decline in the Denver aquifer averaged about 4.1 ft (table 4). A comparison of all changes in water levels from 2010 to 2011 indicate declining water levels with an average decline of 5.0 ft for the Dawson aquifer and a decline of 4.1 ft per year for the Denver aquifer (table 4). A comparison of all changes in water levels from year to year since 2009 indicate declining water levels with an average decline of 4.0 ft per year for the Dawson aquifer and a decline of 2.7 ft per year for the Denver aquifer.

Seven of the wells, three Dawson and four Denver, showed water level declines from the winter high in 2009 to the winter high in 2011. Comparing the seasonal low in 2009 with the seasonal low in 2011 showed declines in water levels in 10 of the wells (4 Dawson, 6 Denver).

#### 2012

In 2012, funding was unavailable until October; therefore, the scope of work was reduced. Even with reduced funding, water levels were able to be measured in February, April, August,

October, and December. Water-level measurements in GRNDAW2, suspended in June 2011, were resumed in October 2012 with permission of the new owner.

Comparison of January 2011 and February 2012 (representing the seasonal high) manual water-level measurements show that water levels declined in 5 of the wells and rose in 13. Rise in the Dawson aquifer averaged 1.2 ft and decline in the Denver aquifer averaged 0.1 ft (table 4). The greatest change from January 2011 to February 2012 in the Dawson aquifer, a rise of about 3.4 ft, was observed in GRNDAW3. The greatest change in the Denver aquifer, a decline of about 4.2 ft was observed in GRNDEV6. A comparison of all changes in water levels from 2011 to 2012 indicate declining water levels with an average decline of 0.3 ft for the Dawson aquifer and a decline of 2.3 ft per year for the Denver aquifer (table 4). A comparison of all changes in water levels from year to year since 2009 indicate declining water levels with an average decline of 2.7 ft per year for the Dawson aquifer and a decline of 2.6 ft per year for the Denver aquifer.

The maximum drawdown (negative difference, or decline, from the January 2009 measurement) of 50.7 ft was observed at well GRNDAW1 during the August 2012 water-level measurements. Increased drawdown was observed during the summers of 2009, 2010, 2011, and 2012, at all of the wells except one (GRNDAW2). Compared to the January 2009 measurement, about 5.5 ft of water-level rise was observed at GRNDAW2 in 2009, and by February 2012, the water level was still 1.1 ft higher than in 2009. Well GRNDAW2 is the shallowest well in the water-level monitoring network, completed 40-160 ft below land surface. Reduced pumping or recharge from precipitation and lawn-irrigation return flows in the vicinity of GRNDAW2 could be contributing to the water-level rise at this location.

#### 2013

In 2013, water levels were measured in February, April, June, August, October, and December. In June 2013, rust scale inside the well casing at GRNDAW2b was knocked loose during a measurement. This caused small particles of rust to clog the faucet and shower screens and sprinkler heads. After the problems were resolved, the well owner declined to continue participation in the monitoring network.

Comparison of the February 2012 and 2013 (representing the seasonal high) manual water-level measurements show that water levels declined in all 19 wells. Decline in the Dawson aquifer averaged 7.0 ft and decline in the Denver aquifer averaged 9.4 ft (table 4). The greatest decline from February 2012 to 2013 in the Dawson aquifer of about 11.43 ft was observed in GRNDAW3, and the greatest decline in the Denver aquifer of about 13.5 ft was observed in GRNDEV4. The greatest seasonal decline in water level observed during this study occurred between February 2012 and February 2013. Comparison of all year-to-year (2012 to 2013) changes in manual water-level measurements for all wells in an aquifer indicates a rise in both aquifers. Rise in the Dawson aquifer averaged 0.6 ft and rise in the Denver aquifer averaged 0.6 ft (table 4). A comparison of all changes in water levels from year to year since 2009 indicate declining water levels with an average decline of 1.6 ft per year for the Dawson aquifer and a decline of 1.7 ft per year for the Denver aquifer.

Water levels measured at GRNDEV6 are consistently lower than nearby wells by as much as 200 ft. Well GRNDEV6 has the deepest completion of all other wells in the network, completed 580-680 ft below land surface.

#### 2014

In 2014, water levels were measured in February, April, June, and August, and October. In June 2014, GRNDAW1C was equipped with an In-Situ Aqua TROLL 200 transducer set to automatically measure and record the depth to water, water temperature and specific conductance at hourly intervals. Due to a program error, specific conductance was not recorded between August and October 2014 (Appendix 1).

Comparison of the February 2013 and 2014 (representing the seasonal high) manual water-level measurements show that water levels rose in 18 wells of the 19 wells. Rise in the Dawson aquifer averaged 5.5 ft and rise in the Denver aquifer averaged 6.2 ft (table 4). The greatest rise from February 2013 to 2014 in the Dawson aquifer of about 6.5 ft was observed in GRNDAW6, and the greatest rise in the Denver aquifer of about 14.3 ft was observed in GRNDEV2. Comparison of all year-to-year (2013 to 2014) changes in manual water-level measurements for all wells in an aquifer indicates a rise in both aquifers. Rise in the Dawson aquifer averaged 3.7 ft and rise in the Denver aquifer averaged 3.3 ft (table 4). A comparison of all changes in water levels from year to year since 2009 indicate declining water levels with an average decline of 0.2 ft per year for the Dawson aquifer and a decline of 0.6 ft per year for the Denver aquifer.

The observed rise in the seasonally high water levels is most likely due to the increased precipitation that occurred during the fall and winter of 2013 (http://www.crh.noaa.gov/bou/?n=denclim\_monthly\_annual).

Analysis of the continuous measurements of water level and selected water-quality properties collected from GRNDAW1C from June 13 through December 31, 2014 shows the water level ranged from 59.27 (December 24) to 89.06 ft below land surface (July 9), and the specific conductance ranged from 752 (October 19, 20, 21, and 22) to 852  $\mu$ S/cm (December 30 and 31) (Appendix 1). The greatest depth to water of 89.06 ft below land surface observed on July 9, 2014 most likely represents a water level that was observed when the pump was running. The rise in specific conductance between October 2014 and January 2015 corresponds with a rise in water level.

#### 2015

In 2015, water levels were measured in February, June, and October. The transducer installed in GRNDAW1C was maintained to automatically measure and record the depth to water, water temperature, and specific conductance at hourly intervals (Appendix 1).

Comparison of the February 2014 and 2015 (representing the seasonal high) manual water-level measurements show that water levels rose in 15 of the 19 wells (table 3). Water levels rose in all of the wells in the Dawson aquifer averaging an increase of 1.9 ft (table 4). Changes in water levels in the wells in the Denver aquifer were mixed. Water levels rose in four wells (GRNDEV1, GRNDEV5, GRNDEV7, and GRNDEV8) and declined in four wells (GRNDEV2, GRNDEV3, GRNDEV4, and GRNDEV6) with an average decline of 0.5 ft (table 4). The greatest rise from February 2014 to 2015 in the Dawson aquifer of about 3.5 ft was observed in GRNDAW1C, and the greatest rise in the Denver aquifer of about 0.8 ft was observed in GRNDEV7 and GRNDEV8 (table 3). The greatest decline from February 2014 to 2015 in the Denver aquifer of about 4.7 ft was observed in GRNDEV6. Comparison of all year-to-year (2014 to 2015) changes in manual water-level measurements for all wells in an aquifer indicates a rise

in both aquifers. Rise in the Dawson aquifer averaged 3.5 ft and rise in the Denver aquifer averaged 2.5 ft (table 4). A comparison of all changes in water levels from year to year since 2009 indicate an average increase of 0.3 ft per year for the Dawson aquifer and a decline of 0.2 ft per year for the Denver aquifer.

Water levels in June were higher than in February in all wells except for GRNDEV6. The observed rise in water levels is most likely due to the increased precipitation that occurred during the spring of 2015 (http://www.wrcc.dri.edu/cgi-bin/cliMAIN.pl?co1401). Water levels in most of the wells in the Douglas County network also were higher in June than in February suggesting that the observed rise in water levels in Grandview Estates is not a local event.

Analysis of the continuous measurements of water level and selected water-quality properties collected from GRNDAW1C from January 1 through December 31, 2015 shows the water level ranged from 53.64 (December 31) to 85.96 ft below land surface (October 12), and the specific conductance ranged from 823 (August 6) to 997  $\mu$ S/cm (November 7,8,9, and 10). The rapid decrease in specific conductance observed in late February and mid-April corresponds with increased pumping and a short term drop in water level at the site. The steady decrease in specific conductance observed late June through early August corresponds with a decrease in the water level at the site.

#### 2016

In 2016, water levels were measured in February, June, October, and December. Measurements were suspended at one well in the Denver aquifer (GRNDEV5) in February 2016 when the property could no longer be accessed. The transducer installed in GRNDAW1C was maintained to automatically measure and record the depth to water, water temperature, and specific conductance at hourly intervals (Appendix 1).

Comparison of the February 2015 and 2016 (representing the seasonal high) manual water-level measurements show that water levels rose in all 18 wells (table 3). Water levels rose in all of the wells in the Dawson aquifer averaging an increase of 5.9 ft (table 4). Water levels rose in all of the wells in the Denver aquifer averaging an increase of 7.5 ft (table 4). The greatest rise from February 2015 to 2016 in the Dawson aquifer of about 9.1 ft was observed in GRNDAW3, and the greatest rise in the Denver aquifer of about 9.9 ft was observed in GRNDEV2 (table 3). Comparison of all year-to-year (2015 to 2016) changes in manual water-level measurements for all wells in an aquifer indicates a rise in both aquifers. Rise in the Dawson aquifer averaged 3.1 ft and rise in the Denver aquifer averaged 3.4 ft (table 4). A comparison of all changes in water levels from year to year since 2009 indicates an average increase of 0.1 ft per year for the Dawson aquifer and a decrease of 0.7 ft per year for the Denver aquifer (table 4).

The highest water levels observed since 2009 occurred during the spring of 2016 in nine of the wells (GRNDAW2, GRNDAW4, GRNDAW1A, GRNDAW1C, GRNDAW1D, GRNDAW1E, GRNDAW1F, GRNDEV1, and GRENDEV7) (table 2). The second highest water levels observed since 2009 occurred during the spring of 2016 in three wells (GRNDAW6, GRNDAW1B, GRNDEV8) (table 3). Water levels in June were equal to or higher than in February in five wells (GRNDAW2, GRNDAW6, GRNDEV3, GRNDEV6, GRNDEV7 (table 3). The observed rise in water levels may be related to above average precipitation that occurred during March and April 2016 (http://www.wrcc.dri.edu/cgi-bin/cliMAIN.pl?co1401). Water

levels in several of the wells in the Douglas County network also were higher in June than in February suggesting that the observed rise in water levels in Grandview Estates is not a local event.

Analysis of the continuous measurements of water level and selected water-quality properties collected from GRNDAW1C from January 1 through December 31st, 2016 shows the water level ranged from 51.15 (April 30) to 86.48 ft below land surface (August 17) ,and the specific conductance ranged from 911 (February 25) to 986  $\mu$ S/cm (August 17).

Analysis of the continuous water level measurements collected from GRNDAW4 from January 1 through December 31st, 2016 shows the water level ranged from 40.40 (April 30) to 66.77 ft below land surface (September 29). Analysis of the continuous measurements of water level collected from GRNDEV3 from January 1 through December 31st, 2016 shows the water level ranged from 115.63 (May 3) to 180.84 ft below land surface (May 23).

#### 2017

In 2017, water levels were measured in February, April, and June. Two new wells (GRNDAW7 and GRNDAW8) were added to the network in February. The transducer installed in GRNDAW1C was maintained to automatically measure and record the depth to water, water temperature, and specific conductance at hourly intervals (Appendix 1, Appendix 1b). Comparison of the February 2016 and 2017 (representing the seasonal high) manual water-level measurements show that water levels declined in 15 wells and rose in 3 (GRNDAW2, GRNDAW 6, and GRNDEV7) (table 3). Water levels in wells in the Dawson aquifer declined an average of 2.7 ft (table 4). Water levels in wells in the Denver aquifer declined an average of 6.1 ft (table 4). The greatest decline from February 2016 to 2017 in the Dawson aguifer of about 4.4 ft was observed in GRNDAW3, and the greatest decline in the Denver aquifer of about 13.3 ft was observed in GRNDEV4 (table 3). Comparison of all year-to-year (2016 to 2017) changes in manual water-level measurements for all wells in an aquifer indicates a decline in water level in both aguifers. Decline in the Dawson aguifer averaged 7.3 ft and decline in the Denver aguifer averaged 13.2 ft (table 4). A comparison of all year to year changes in water levels since 2009 indicates an average increase in water level in the Dawson aquifer of 0.1 ft per year and an average decline in water level in Denver aquifer of 0.7 ft per year (table 4).

The highest water levels observed since 2009 occurred during the spring of 2017 in four of the wells (GRNDAW2, GRNDAW7, GRNDAW8, and GRENDEV7) (table 2). Because GRNDAW7 and GRNDAW8 were added to the network in 2017 (table 3), the highest observed water levels in these wells is simply caused by the short period of record at these wells. The first water levels were measured in February, which are typically the highest water levels observed throughout the year. Water levels at GRNDAW2 and GRNDEV7 have been on a steady rise since the fall of 2013 with the previous highest water level in both wells occurring in June 2016.

The lowest water levels measured since 2009 were observed in three wells (GRNDAW7, GRNDAW8, and GRNDEV 6) in August 2017 (table 2). In all cases, these lowest observed water levels are most likely not representative of changes in the local aquifer system. For wells GRNDAW7 and GRNDAW8, water levels represent only a short period of record since 2017 (table 3). The lowest measured water level of 301.73 ft below land surface in GRNDEV6 (table

3) may be affected by recent pumping of the well as noted by the "R" in the water level status column.

Analysis of the continuous measurements of water level and selected water-quality properties collected from GRNDAW1C from January 1 through August 10th, 2017 shows the water level ranged from 51.15 (April 30) to 71.23 ft below land surface (May 24) ,and the specific conductance ranged from 911 (February 25) to 968  $\mu$ S/cm (June 6 and 7).

Analysis of the continuous water-level measurements collected from GRNDAW4 from January 1 through August 10h, 2017 shows the water level ranged from 44.30 (April 7) to 72.04 ft below land surface (July 12). Analysis of the continuous measurements of water level collected from GRNDEV3 from January 1 through August 10th, 2017 shows the water level ranged from 126.01 (April 7) to 180.85 ft below land surface (June 15).

## Water Quality and Groundwater Age

Water-quality results for the sampled wells are available from the USGS NWIS website for water-quality data (http://nwis.waterdata.usgs.gov/co/nwis/qwdata) and selected results are presented in table 5. Observed water quality for these two wells is generally good with no detections of volatile organic compounds or pesticides in the shallower of the two wells (DAWMAS07). The sample from DENMAS08 was not analyzed for volatile organic compounds or pesticides. In general, groundwater quality in the shallower well contains total dissolved solids, major-ion concentrations, and a dissolved-oxygen concentration greater than those in the deeper well (DENMAS08). Nitrate, reported as nitrate plus nitrite as nitrogen, was detected at a concentration of 5.8 milligrams per liter (mg/L) in well DAWMAS07, which is less than the U.S. Environmental Protection Agency drinking water standard of 10 mg/L. Nitrate concentrations, reported as nitrate plus nitrite as nitrogen, in well DENMAS08 were below the analysis detection limit of 0.06 mg/L. Groundwater age (time since recharge) was estimated for these two wells on the basis of tritium concentrations and on the basis of chlorofluorocarbon (CFC) concentrations in the groundwater compared to historical graphs of CFC concentrations in the atmosphere. Tritium was detected in samples from both wells, indicating that the sampled groundwater or a portion of the sampled groundwater was less than 50 years in age. Comparison of groundwater CFC concentrations to historic atmospheric CFC concentrations indicates that the sample from well DAWMAS07 was recharged in about 1990 (estimated groundwater age of 15 years before the sample date, fig. 4) and that the sample from well DENMAS08 was recharged in about 1970 (estimated groundwater age of 35 years before the sample date, fig. 5) using a piston-flow model.

# Summary

A water-level monitoring network domestic wells was established in Grandview Estates in 2009 by the USGS and the GERWCD. Between 2009 and 2014, 21 wells have been monitored for some portion of the study period. Since 2009, water levels were measured in the established Grandview Estates monitoring network on a regular basis; ranging from triennial to bi-monthly. In 2004 and 2005, two domestic wells in Grandview Estates were sampled by the USGS

NAWQA program. Results from the water-level monitoring indicate that during the summers water levels were less than initial conditions in January 2009, and water levels were lowest in the summer of 2012. Summer water-level declines are expected during the lawn-irrigation season when domestic wells are pumped for outdoor water use. Water-level rise is typically observed in all wells from September through May. This rise is likely in response to the reduction in pumping during the winter months and possibly in response to recharge from above average precipitation during the fall and spring. Water-level results indicate that potentiometric conditions in bedrock aquifers beneath Grandview Estates respond to changing pumping and climatic conditions, and water-quality results indicate that relatively young waters are present at depths as great as 400 ft below land surface. A comparison of all changes in water levels from year to year since 2009 indicate an average increase of 0.1 ft per year for the Dawson aquifer and a decrease of 0.7 ft per year for the Denver aquifer (table 4).

Water-quality is generally good for the two sampled wells. At the shallower well (DAWMAS07), total dissolved solids, major ion, dissolved oxygen, and nitrate concentrations were greater than at the deeper well (DENMAS08). Groundwater age was estimated from groundwater tritium and CFC concentrations. A groundwater age (years since recharge) of about 15 years before the sample date was estimated for well DAWMAS07 (recharge date of about 1990), and a groundwater age of about 35 years before the sample date was estimated for well DENMAS08 (recharge date of about 1970).

Table 4. Average change in seasonally high water level and average yearly change in water level for all measurements Grandview Estates, Douglas County, Colorado.

Average change in seaso	onally high (Februai	ry) water level (ft)
Voor to woor period	Ad	quifer
Year-to-year period -	Dawson	Denver
2009 to 2010	-1.8	8.1
2010 to 2011	-5.6	-7.3
2011 to 2012	1.2	-0.1
2012 to 2013	-7.0	-9.4
2013 to 2014	5.5	6.2
2014 to 2015	1.9	-0.6
2015 to 2016	5.9	7.5
2016 to 2017	-2.7	-6.1
Average all measurments	0.7	0.4

Average year-to-year change in water level for all measurments (ft)			
Year-to-year period	Aquifer		
	Dawson	Denver	
2009 to 2010	-2.5	-1.3	
2010 to 2011	-5.0	-4.1	
2011 to 2012	-0.3	-2.3	
2012 to 2013	0.6	0.6	
2013 to 2014	3.7	3.3	
2014 to 2015	3.5	2.5	
2015 to 2016	3.1	3.4	
2016 to 2017*	-7.3	-13.2	
Average all measurments	0.1	-0.7	

<sup>\*</sup>Does not represent a full year of data. Water levels from October and December 2017 are not included in this report.

Table 5. Water-quality results for selected wells in Grandview Estates, Douglas County, Colorado.

[Site identification numbers in this table are hyperlinked directly to the data on NWISWeb. Abbreviations:: E, concentration estimated below method detection limit; < less than; -, no data]

Parameter Value		ue
USGS Site ID	393227104490101	393227104493001
Local well name	DAWMAS07	DENMAS08
Sample date	12/10/2004	10/13/2005
Sample time	10:15	12:00
Colorado well-permit number	102174	149947
Total depth, in feet below land surface	340	441
Depth to top of screened interval, in feet below land surface	300	361
Depth to bottom of screened interval, in feet below land surface	340	441
Temperature, water, degrees Celsius	12.5	14.7
Depth to water level, feet below land surface	112.78	-
Specific conductance, microsiemens per centimeter at 25 degrees Celsius	934	354
Dissolved solids, milligrams per liter	610	220
Dissolved oxygen, water, unfiltered, milligrams per liter	4.5	0.2
pH, water, unfiltered, field, standard units	6.9	8.3
pH, water, unfiltered, laboratory, standard units	7.5	7.1
Ammonia, water, filtered, milligrams per liter as nitrogen	E 0.02	0.09
Ammonia, water, filtered, milligrams per liter as NH4	E 0.03	0.11
Nitrite, water, filtered, milligrams per liter as nitrogen	< 0.008	< 0.008
Nitrate plus nitrite, water, filtered, milligrams per liter as nitrogen	5.79	< 0.06
Total nitrogen, water, filtered, analytically determined, milligrams per liter	5.78	0.09
Orthophosphate, water, filtered, milligrams per liter	0.172	E 0.012
Orthophosphate, water, filtered, milligrams per liter as phosphorus	0.056	E 0.004
Organic carbon, water, filtered, milligrams per liter	1.8	0.7
Bicarbonate, in milligrams per liter	290	158
Alkalinity, water, filtered, field, milligrams per liter as calcium carbonate	239	132
Hardness, water, milligrams per liter as calcium carbonate	440	63
Calcium, water, filtered, milligrams per liter	146	21.8
Magnesium, water, filtered, milligrams per liter	18.8	2.02
Sodium, water, filtered, milligrams per liter	30.7	54.5
Potassium, water, filtered, milligrams per liter	3.38	3.46
Chloride, water, filtered, milligrams per liter	91.6	10.1
Sulfate, water, filtered, milligrams per liter	101	34.2
Fluoride, water, filtered, milligrams per liter	0.55	1.04
Silica, water, filtered, milligrams per liter as SiO2	39.9	11
Arsenic, water, filtered, micrograms per liter	2.2	0.42
Copper, water, filtered, micrograms per liter	4.9	9
Iron, water, filtered, micrograms per liter	8	< 6
Lead, water, filtered, micrograms per liter	0.25	0.1
Manganese, water, filtered, micrograms per liter	0.2	19.1
Selenium, water, filtered, micrograms per liter	10.6	< 0.08
Uranium (natural), water, filtered, micrograms per liter	20.3	1.78
Deuterium/Protium ratio, water, unfiltered, per mil	-104	-109
Oxygen-18/Oxygen-16 ratio, water, unfiltered, per mil	-13.69	-14.38
Tritium, water, unfiltered, picocuries per liter	43.2	7
Tritium 2-sigma combined uncertainty, water, picocuries per liter	2.6	1
Basis for piston-flow age estimation	CFC-12, CFC-113	CFC-12, CFC-113
Estimated age from chlorofluorocarbon concentrations, in years before		
sample date	15	35
Estimated recharge date from chlorofluorocarbon concentrations	1990	1970
